

1. Create a new encrypted key value map

Create the encrypted KVM

1. On the left navigation menu, click **Admin > Environments > Key Value Maps**.
2. Select the **test** environment.
3. Click **+Key value map**, and use the following properties:

Property	Value
Name	ProductsKVM
Encrypted	<i>selected</i>

Click **Add**.

Populate the KVM

1. Select **ProductsKVM**, and then click **+** to add each of the following entries:

Name	Value
backendId	svcacct
backendSecret	UNdrDxeQ82

The key and value names are case-sensitive. Ensure that you do not include any leading or trailing spaces or newlines in your keys or values.

2. Your KVM should look like this:

Environments > Key value maps > test > **ProductsKVM**

ProductsKVM	
All ▼	
KEY	VALUE
backendId	svcacct
backendSecret	UNdrDxeQ82

This is an encrypted KVM, but you can see the values. The values are being shown client-side in your browser. If you refresh your browser page, you will see that the backendId and backendSecret values cannot be viewed.

Repeat for prod environment (optional)

- Create the same KVM with the same entries in the **prod** environment if you want to be able to promote your API to production.
